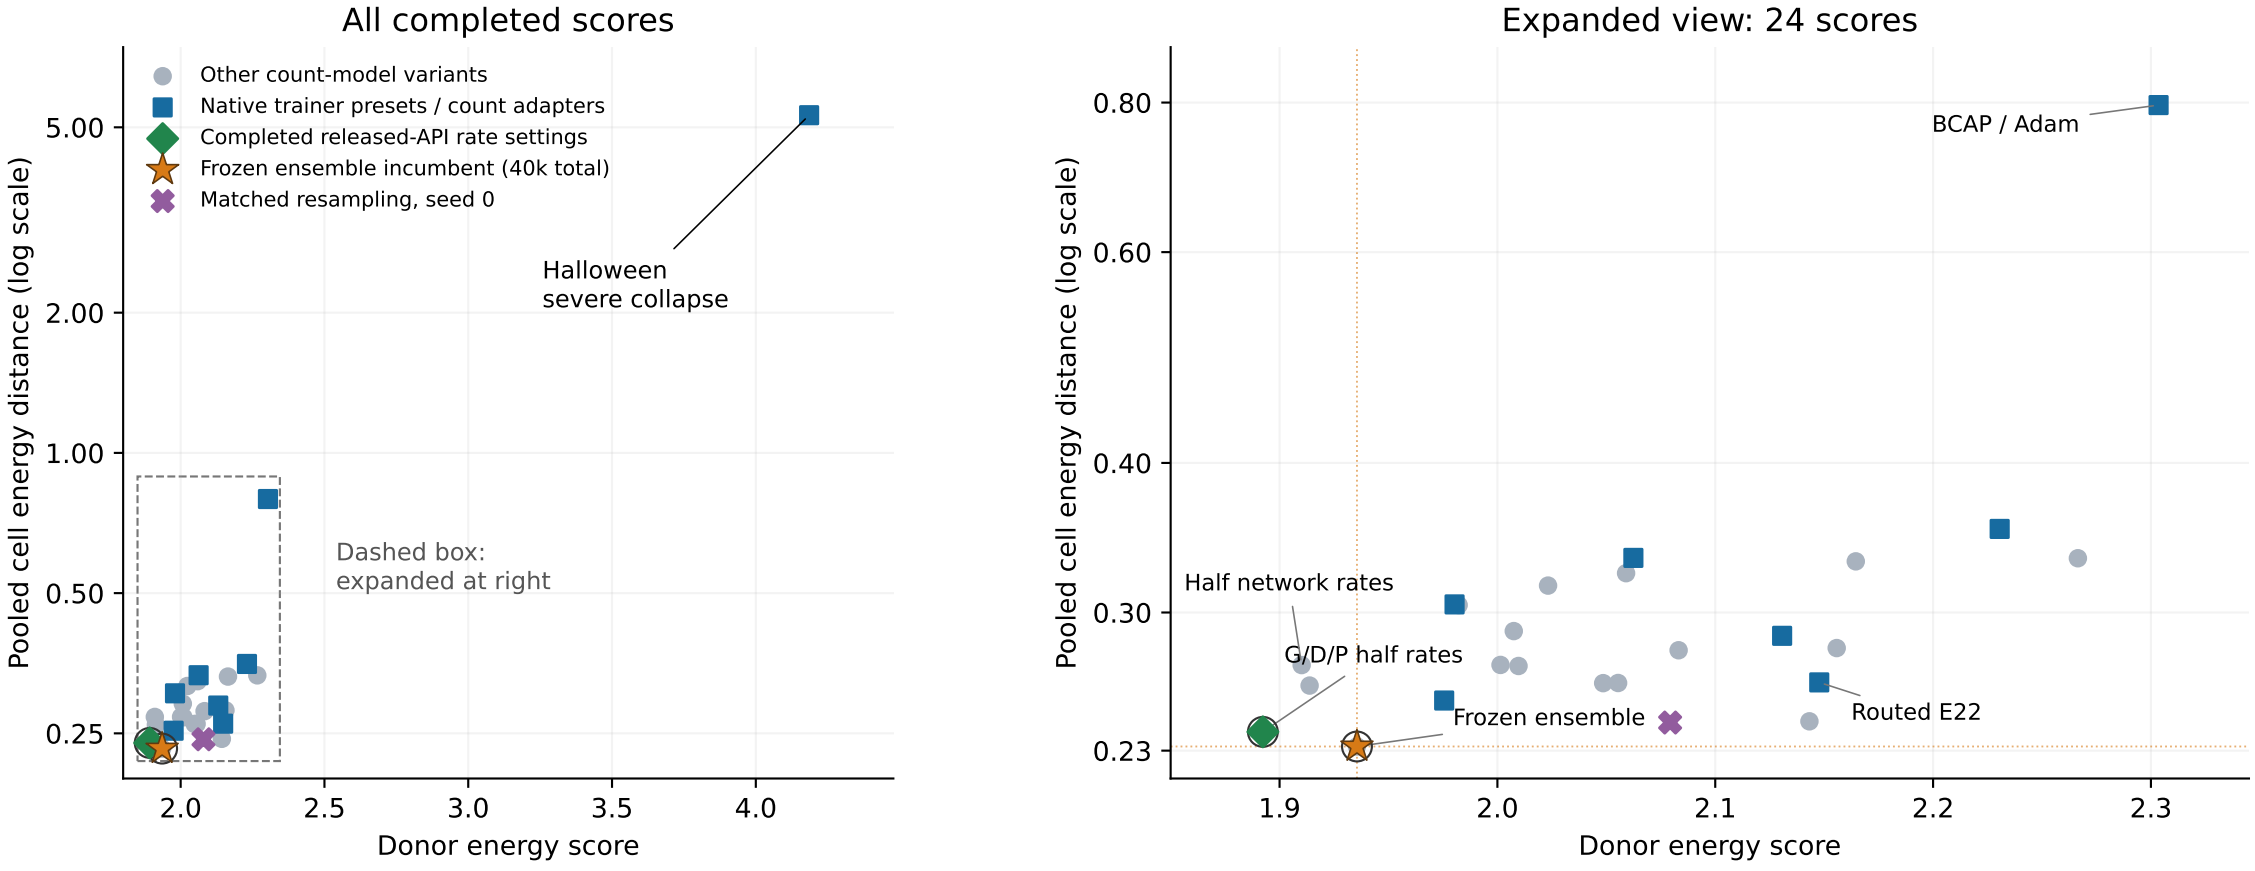
Measured energy and distribution tradeoffs

25 completed pure-count seed-0 comparisons. Lower is better on both axes.

Released-API rate settings appear only after independent audits of their completed endpoints.



The first rate setting improves energy, but its cell distance remains above the frozen incumbent.

Seed-0 tuning only. The original ensemble failed joint confirmation on seeds 1 and 2; new rates are unconfirmed.

Four adaptive calibration donors; 20 evaluation donors excluded. Pareto rings describe saved scores, not promotion.
